Abstract. High energy optimal ion microprobes comprised of new compact magnetic quadrupole lenses (Lafayette Quadrupole Lens) are numerically investigated. The smallest beam spot size and appropriate radii of object and divergence slits are presented for different emittances and compared with the corresponding parameters of the Oxford triplet for the same total length. The parameters of the calculated microprobes include demagnification, the magnetic field in the lenses and the coefficients of spherical and chromatic aberrations for several quadrupole system configurations including the doublet, the Lafayette symmetric triplet, the Russian magnetic quadruplets and sextuplets.

Keywords: Ion microprobe; Quadrupole lens; Spherical aberration; Chomatic aberration;Doublet; Triplet; Russian quadruplet.

INTRODUCTION

In a nuclear microprobe the focusing system is an essential component which determines the beam spot size, i.e. the microprobe resolution, which depends on the spherical and chromatic aberrations. A small beam cross section at the target is the most important of the many conflicting requirements imposed on the beam. Focusing of ion beams of MeV energy is mostly accomplished by magnetic quadrupole lenses in different configurations: doublet, triplet, quadruplet and quintuplet. The most popular systems are the Oxford triplet (OT) and Russian quadruplet (RQ). Using the object and divergence slits we can find for every emittance the optimal size of slits which give the minimum spot size for a given system.

All possible configurations of lenses for the same total length (the distance from the object slit to the target) and for a different length of lenses have different aberrations, demagnifications and magnetic fields on the poles of the quadrupole lenses. In this paper we compare the coefficients of the spherical and chromatic aberrations, demagnifications and magnetic fields for different configurations of quadrupole lenses for two lenses: the Oxford magnetic lens with 0.1 m length and 0.0075 m lens aperture and the Lafayette magnetic lens with 0.04 m length and 0.0035 m lens aperture.

OPTIMIZATION AND NOTATIONS

We have performed the special program of optimizing analytical and numerical calculations to obtain the best design for our system. Beam focusing is understood as the result of non-linear motion of a set of particles [1-3]. As a result of this motion, we have the beam spot on the target. The set has a volume (the phase volume, or emittance). For a given brightness, the phase volume is proportional to the beam current and vice versa. The beam has an envelope surface. All particles of the beam are located inside of this surface, inside of this beam envelope. For the same phase volume (or beam current) the shape of the beam envelope can be different. We say the beam envelope is optimal if the spot size on the target has a minimum value for a given emittance. The beam of a given
emittance \( em_{xy} = em_x em_y \) is defined by a set of two matching slits: objective and divergence slits. For a given emittance \( em_{xy} \), the shape of the beam envelope is the function of the half-widths \( r_{1x} \) and \( r_{1y} \) of the objective slit and of the distance \( l_{1z} \) between two slits. The half-widths \( r_{2x} \) and \( r_{2y} \) of the second (divergence) slit are determined by the expressions:

\[
r_{2x} = \frac{em_x l_{1z}}{r_{1x}}, \quad r_{2y} = \frac{em_y l_{1z}}{r_{1y}}.
\]

The optimal parameters \( r_{1x}, r_{1y}, r_{2x}, r_{2y}, \) and \( l_{1z} \) determine the optimal beam envelope or the optimal matching slits [4].

The probe-forming system consists of two systems: the matching slit system and the focusing system. In many cases the focusing system has two field parameters (two excitations) and several parameters of its geometry. The two conditions of stigmatism determine two excitations as a function of the geometry. For a given geometry and for a given emittance we can find the corresponding optimal matching slits. The geometry, which gives the possibility to obtain a smallest spot size, is the optimal geometry. For this geometry and for the optimal matching slits we find the optimal excitations giving the minimum spot size. The optimal probe-forming system comprises the optimal excitations, optimal matching slits and optimal geometry. For any given emittance we find the parameters of the optimal probe-forming system. We consider the non-linear motion of the beam accurate to terms of 3rd order.

All geometry notations are shown in Fig.1. We use the following notations for the distances in a system of \( n \) quadrupole lenses: \( s_j \) is the effective spacing between the \( j \)-th lens and \( (j+1) \)-th lens; \( l_j \) is the effective length of the \( j \)-th lens; \( a \) is the effective object distance (the effective distance between the object slit and the first lens); \( g \) is the effective working (or image) distance; \( l_t \) is the total length of the system (the distance between the object and the image). The demagnifications in the \( xoz \) and \( yoz \) planes are \( d_x \) and \( d_y \), respectively.

An ion optical system of minimum focal length must be used to obtain a microprobe with maximum decrease of the beam diameter. The lower limit on the focal length is determined by the lowest attainable boundary of working distance \( g \) and the smallest possible lens length and probe length. The lower limit on the lens length is determined by the maximum possible magnetic induction at a pole or field strength at an electrode and by the lens construction.

Taking into account chromatic and spherical aberrations, assuming that \( r_2 >> r_1 \), we can write down an approximate expression for the absolute value of the beam half-width \( x_e \) at the target for \( y_0 = 0 \) and \( y'_0 = 0 \):

\[
|x_e| = \left| \frac{1}{d_x} \right| \left| \frac{C_{px}}{C_{sx}} \delta_E \right| x_{0x}^{\max} + \left| C_{sx} \right| \left| \frac{C_{px}}{C_{sx}} \delta_E \right|^3
\]

or

\[
|x_e| = \frac{em_x}{|x'_e|} + \left| \frac{C_{px}}{C_{sx}} \delta_E \right| |x'_e| + \left| C_{sx} \right| |x'_e|^3
\]

Here

\[
c_{px} = \frac{C_{px}}{d_x}, \quad c_{sx} = \frac{C_{sx}}{d_x}, \quad x'_e = d_s x'_0, \quad \delta_E = \frac{\Delta E}{E}
\]

We use the following notations:

- \( C_{sx} \) and \( C_{sy} \) are the spherical aberration coefficients in the object space;
- \( C_{px} \) and \( C_{py} \) are the chromatic aberration coefficients in the object space;
- \( em_x \) and \( em_y \) are the emittances of the beam in the \( x \)- and \( y \)-planes;
- \( c_{px} \) and \( c_{py} \) are the chromatic aberration coefficients in the image space in the \( x \)- and \( y \)-planes;
- \( c_{sx} \) and \( c_{sy} \) are the spherical aberration coefficients in the image space in the \( x \)- and \( y \)-planes;
- \( x'_e \) and \( y'_e \) are the divergences in the image space.

**DIFFERENT TWO PARAMETRIC CONFIGURATIONS OF QUADRUPOLE LENSES**

Focusing of ion beams of MeV energy until now is mostly accomplished by magnetic quadrupole lenses in different configurations: doublet, triplet, quadruplet, quintuplet and sextuplet.

In many cases the focusing system has two field parameters (two excitations) – two parametric focusing system. The simplest two parametric quadrupole system is a doublet. The second simplest two parametric focusing system after doublet configuration is a two parametric triplet. There are two different configurations of this triplet.

The first one is the Oxford configuration. In this triplet focusing and defocusing capabilities of the lenses in one plane alternate F-D-F whereas the lens strengths are ordered as A-A-B.

The second two parametric triplet has the Lafayette configuration. In this configuration focusing and defocusing capabilities of the lenses in one plane also alternate F-D-F whereas the lens strengths are
ordered as A-B-A. Both configurations are considered with equal lenses \((l_1 = l_2 = l_3 = l)\) and drift spaces \(s_1\) and \(s_2\).

The next two parametric focusing system is the Russian quadruplet with \(l_1 = l_2, \quad l_3 = l_4 = l, \quad s_3 = s_1\). In this quadruplet focusing and defocusing capabilities of the lenses in one plane alternate F-D-F-D whereas the lens strengths are ordered as A-B-A-B-A.

Two triplets form a two parametric Russian sextuplet [5]. In this sextuplet focusing and defocusing capabilities of the lenses in one plane alternate F-D-F-D-F-D whereas the lens strengths are ordered as A-B-A-A-B-A.

**NUMERICAL RESULTS**

The results of calculations for the main parameters of the doublet \((s_1 = 2.5\text{cm})\), the Lafayette configuration of a nonseparated \((s_1 = s_2 = 2.5\text{cm})\) and separated \((s_1 = 2.9\text{m}, \quad s_2 = 2.5\text{cm})\) triplet, Russian nonseparated \((s_1 = s_2 = s_3 = 2.5\text{cm})\) and separated \((s_1 = s_2 = s_3 = 2.5\text{cm}, \quad s_2 = 5\text{m})\) quadruplet and separated \((s_1 = s_2 = s_4 = s_5 = 2.5\text{cm}, \quad s_3 = 2.8\text{m})\) sextuplet comprised from Lafayette lenses are shown in Tables 1, 2 and 3. For the comparison in the Table 1 the same parameters of the Oxford triplet \((s_1 = s_2 = 6\text{cm})\) are given. All considered systems have the same total length \(l = 6.25 \text{ m}\) and the same working distance \(g = 0.18 \text{ m}\).

From the Table 1 it follows that all coefficients of spherical and chromatic aberrations of all investigated systems comprised from Lafayette lenses are approximately the same and significantly less than the appropriate maximum coefficients of the Oxford triplet.

Optimal slits and appropriate spot size for a few systems and for the emittance \(em_{xy} = 10^{-18} \text{ m}^2\) are given in the Table2.

In the Table 3 optimal slits and appropriate spot size for a few systems are given for the emittances at which the minimum width of one of the object slits is approximately \(1 \mu\text{m}\).

CONCLUSIONS

The smallest beam spot size and appropriate radii of object and divergence slits of high energy ion microprobe systems comprised of Lafayette lenses are obtained for different emittances and compared with the corresponding parameters of the Oxford triplet for the same total length.

Separated Lafayette triplet and separated Russian quadruplet and sextuplet must be used if we want to obtain spot size less in the range 100nm×100nm – 15nm×15nm.
